Introduction
Retrocaval ureter is one of the rarest congenital anomalies. Here the ureter deviates medially and passes behind the inferior vena cava winding about and crossing in front of it from medial to lateral side. However this is due to a developmental anomaly of the embryonic veins forming the IVC rather than an anomaly of the ureteric development. Most patients present with loin pain. Occasionally calculi may form above the obstruction.

Case report
A 53-year old man developed right abdominal pain. Abdominal ultrasonography showed right hydronephrosis and hydroureter with several stones inside the dilated upper ureter. There were gall stones too. An IVU did not delineate the upper urinary tract clearly due to poor renal function (Figure 1). The CT IVU showed a retrocaval ureter with several stones lodged inside the dilated upper ureter (Figure 2).

Surgical intervention is indicated in the presence of functionally significant obstruction leading to pain or other complications like stone formation or urosepsis. Right ureter was approached by a right subcostal incision below the twelfth rib. The proximal and distal ureteric segments were isolated (Figure 3). The ureter medial to and posterior to the IVC was gently separated. After division of the ureter the stones were removed and the spatulated distal segment was anastomosed to the proximal dilated segment using 3-0 polyglactin sutures across a 6 Fr double J ureteric stent anterior and lateral to the IVC. Patient had an uneventful recovery and the ureteric stent was removed after 6 weeks.
Retrocaval ureter is classified into two types based on its radiographic appearance and the site of crossing the IVC (2). In type I as in our case, the ureter crosses the IVC at the level of the third lumbar vertebra and has a fish hook shaped (S shape) appearance. In the type II, the ureter crosses the IVC at a higher level near the renal pelvis. The curve is smooth and sickle shaped and degree of hydronephrosis is less severe or non-existent. Almost all symptomatic cases of retrocaval ureter appear to be type I anomalies (3). Treatment of the retrocaval ureter entails anteriorisation of the ureter and ureteroureterostomy. If there are stones, those should be removed.
